The combining of two identical molecules creates dimer, the key member in the family of polymers used in the parylene conformal coating process. This dimer (di-para-xylene) is heated to approximately 150°, resulting in conversion to a gaseous monomer. Coating thicknesses and uniformity are both controlled by the amount and the purity of the dimer used. dimer is over 99% pure, the purest available, resulting in a more truly conformal coating, providing better protection for your substrates - meaning less product failures and leaving you with a higher profit margin.

Parylene Coating Services, Inc. offers two parylene dimer variations:

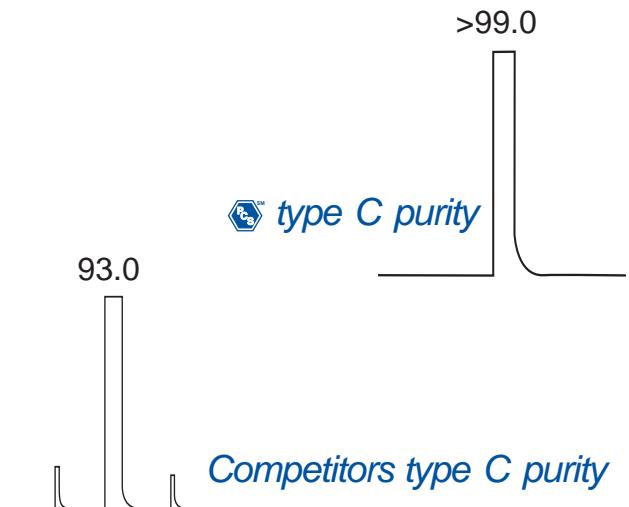

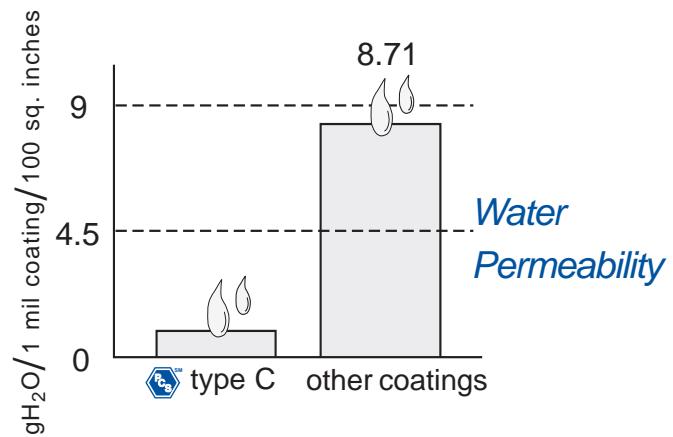

The most widely used,  
good electrical and  
physical properties.

Selected for its high  
dielectric strength and  
where greater  
coating penetration  
is needed.

*Purity is everything in Parylene
